

Sustainable Chemistry for Metal Recycling

Jason B. Love

*EaStCHEM School of Chemistry, University of Edinburgh,
Edinburgh EH9 3FJ, UK.*

Metals are ubiquitous in modern technology and their recycling from sources such as electronic waste, magnets, and high-performance materials is crucial to achieve circular economy visions and to ensure that wastes are both minimised and environmentally benign.¹ In this presentation, the application and significance of coordination and supramolecular chemistry in metal recycling processes will be highlighted.² New routes to the dissolution and selective separation of gold and other metals from electronic waste will be described,³ along with the selective precipitation of light rare-earth and actinide elements using a unique supramolecular encapsulation strategy.⁴ These case studies rationalise the need to understand the mode of action in separations processes at a fundamental chemical level and the ability to exploit ligand design to achieve new and useful separations technologies.
